# SUMMARY

Three efficiency test runs were conducted on an Edwards Engineering Corporation Hydrocarbon Vapor Recovery Unit Model DE 1000 at the March Air Force Base Panero refueling area on 22 and 23 September and 1 October 1981. The recovery system was installed to control JP-4 vapors displaced from the filling of underground tanks. The purpose of the test was to assess compliance with South Coast Air Quality Management District Rule 462 specifying minimum efficiencies for vapor condensation systems. Simultaneous inlet and outlet concentrations were measured with Flame Ionization Detectors (FIDs) and total outlet volume was measured with a Roots meter. Outlet bag samples were analyzed for hydrocarbon constituents with a gas chromatograph, and the inlet constituents needed for the calculations were taken from typical JP-4 vapor analysis. Test results showed efficiencies of 90.7%, 89.9%, and 88.1%, with an arithmetic average of 89.6%. Time weighting the efficiencies (Test Run 2 was longer than Test Runs 1 and 3 combined) shows an average efficiency of 89.7%. Gas chromatograph analysis of outlet vapors showed approximately one-half the constituents to be under C<sub>4</sub> and the other half to be C<sub>4</sub>s.

One test run was conducted at the Pritchard refueling area on 10 October 1981, showing an efficiency of 85.7%. Because only one one-hour test was conducted, the results are statistically less valid than results for the Panero system.

The temperature of the fuel averaged 79.5 degrees F during this test program. This compares well with the maximum recorded fuel temperature during the period from 1978 to 1980, which was 80 degrees F. It is expected that the inlet loading would vary directly with the fuel temperature.

## PREFACE

This test program was conducted by Engineering-Science, Inc. (ES), 125 West Huntington Drive, Arcadia, California 91006, under Air Force Contract No. F33615-80-D-4001, Call Order 013, for the Air Force Occupational and Environmental Health Laboratory, Brooks Air Force Base, Texas.

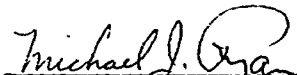

Mr. Thomas Stauffer, AFESC/RDVC, Tyndall Air Force Base, Florida, was the Air Force technical contact.

This report summarizes testing conducted during the period from 22 September to 10 October 1981.

Lt. Joe Ragowicz of March Air Force Base assisted the test crew in access to the test sites and coordination within March Air Force Base.

This report has been reviewed by the Public Affairs Office and is releasable to the National Technical Information Service (NTIS). At NTIS it will be available to the general public, including foreign nationals.

## SECTION I

### INTRODUCTION

The U.S. Air Force installed low temperature condensation vapor recovery units on the underground jet fuel (J2-4) storage tank vents at March Air Force Base, California during 1981. The condensation units were installed to reduce the hydrocarbon vapor emissions that result from vapor displacement during filling of the tanks. The purpose of this task was to measure the collection efficiency and vapor emission rates to satisfy the South Coast Air Quality Management District (SCAQMD) permitting requirements. SCAQMD Rule 462, as amended in 1968, specifies minimum efficiency levels for vapor condensation systems.

Engineering-Science, Inc. (ES), was retained under USAF Contract Number F33615-80-D-4001, Call Order 013, to conduct at least three independent efficiency test runs on one of the condensation units. Three efficiency test runs were conducted, one per day, on the Panero refueling unit at March AFB on 22-23 September, and 1 October 1980. On 8 October an additional test consisting of only one test run was conducted at the March AFB Pritchard refueling area. Because only one test run was performed on the Pritchard unit, the test results are statistically less valid than results for the Panero System.

Field testing was performed by Mr. Michael McDavitt and Mr. James Peterson, supervised by Mr. Donald Holtz and Mr. Lawrence Cottone, all of ES. Mr. Michael Sargeant, also of ES, conducted the gas chromatographic analysis.

Preparation for the first test on 21 September 1981, was witnessed by USAF representative Mr. Tom Stauffer of Tyndall AFB, Florida, Mr. Ken Kitchingman of EPA Region IX in San Francisco, Mr. Philip Lammi of the Air Force Regional Civil Engineering office in San Francisco, and Ms. Christine Metz of the Defense Department in Washington.

South Coast Air Quality Management Rule 462 applies to organic liquid loading facilities that handle more than 20,000 gallons per day of organic liquids having a vapor pressure of 77.5 mm Hg (1.5 psia) or greater under

actual loading conditions. The rule states the following: "An absorber or condensation system which processes the displaced vapor [shall] recover at least 90% by weight of the organic vapors and gases charged to the system." The March AFB liquid loading facilities handle more than 20,000 gallons per day and during the hot summer months the JP-4 vapor pressure may exceed 77.5 mm Hg (1.5 psia).

The vapor recovery efficiency was determined by simultaneously employing flame ionization detection (FID) instruments at both the inlet and outlet sites of the unit. The instruments measured hydrocarbon concentrations and were calibrated with known concentrations of methane ( $\text{CH}_4$ ). The outlet flow rates also were measured and, with the aid of gas chromatographic analysis of inlet and outlet concentrations, mass hydrocarbon flow rates and the efficiency at both inlet and outlet could be determined.

## SECTION II

### PROCESS DESCRIPTION AND CONTROL EQUIPMENT

#### PROCESS DESCRIPTION

Figure 1 illustrates the JP-4 storage system. The JP-4 is received via a pipeline and stored in floating-roof tanks from which it is either gravity fed or pumped to underground storage tanks in the airplane refueling areas. Two refueling areas, Panero and Pritchard, are regularly used at March AFB. The Panero refueling area is provided with 34 underground storage tanks with a capacity of 50,000 gallons per tank. The Pritchard refueling area has only six underground storage tanks (of the same capacity) and is farther from the bulk storage site than Panero.

The Panero refueling area was gravity fed from bulk storage for test runs 1, 2, and 3. Testing was facilitated on these dates at Panero by first pumping fuel to the Pritchard refueling area to create a deficit at the Panero site. Panero was then "topped off" from bulk storage by gravity feed.

When the underground tanks are filled, the displaced vapor volume passes through the vent pipe to the vapor condensor. Fuel flow rates vary from approximately 450 gpm during gravity flow to 670 gpm for pumped flow. Tank fillings and fuel transfers last up to four hours. The fuel flow rates give an approximation of the displaced vapor flow rates.

Because JP-4 constituent vapor pressures change at different rates with temperature changes, the relative composition of the displaced JP-4 vapor is dependent on the liquid fuel temperature. The fuel temperature was measured at noon daily from the Panero and Pritchard refueling areas by USAF personnel. The average fuel temperature for the four test dates was 79.5°F, and the composition of the JP-4 vapors was relatively constant throughout the four test days.

Figure 1. Schematic of the JP-4 Fuel Storage and Vapor Recovery System

Air Force exercises and other activities dictate fuel consumption, and hence the amount of fuel movement required to maintain near capacity-filled tanks. Fuel movement was generally low during the period of the testing. The amount of fuel received at refueling areas on the test dates ranged from 11,000 to 178,000 gallons.

Both refueling area systems are provided with breather valves that relieve excess negative or positive vapor pressures. During Run 4, which was performed at the Pritchard site, it was observed that JP-4 vapors were venting out of the unit's breather valve. Since the breather valve was releasing vapors upstream of the vapor recovery unit, the measured emission rate from the system was lower than actual. This loss in vapors from the breather valve, however, would not have a direct influence on the efficiency of the vapor recovery unit.

#### CONTROL EQUIPMENT

Panero and Pritchard refueling areas are currently both equipped with Edwards Engineering Corporation Hydrocarbon Vapor Recovery Unit Model DE 1000. Figure 2 illustrates the general components and the air vapor flow path.

The vapor recovery unit is a once-through refrigerated condensor designed to maintain temperatures in the coil of -90°F. Displaced JP-4 vapors enter the unit through an 8-inch diameter iron pipe. The vapors first pass through a precooler coil which takes out most of the moisture and lowers the temperature to approximately 35°F.

The vapors then enter into the top of the low temperature condensing coil. The condensor, constructed of a series of finned coils, is designed to allow for some frost buildup at the entry area without impeding vapor flow. Condensate drops fall into a collector bin which drains to a hydrocarbon water separator.

Frost buildup on the condensor coils will clearly interfere with the vapor condensation potential of the system. For this reason, the unit is designed to defrost itself one hour per 24 hours during a period of inactivity.

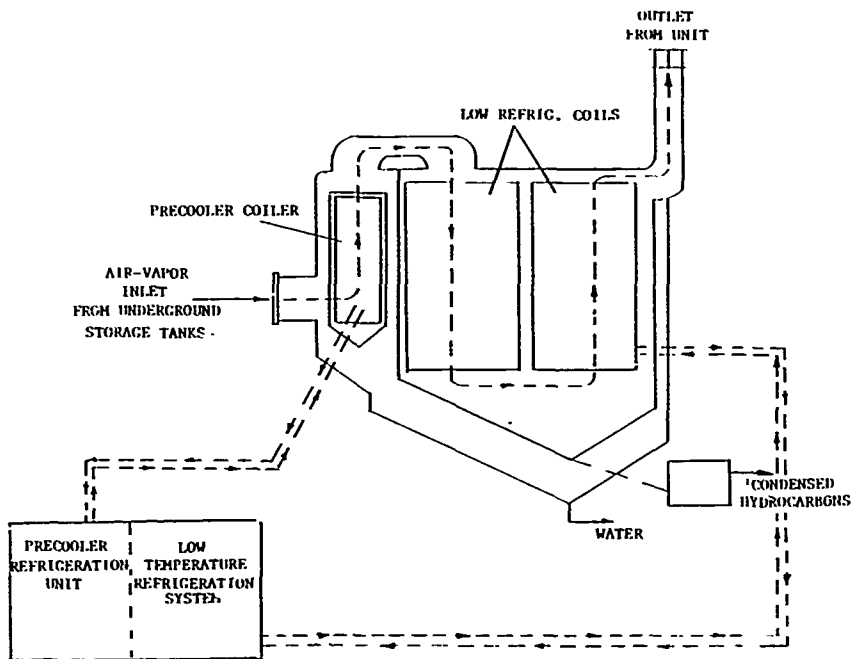

Figure 2. Schematic of Edwards Engineering Corporation Hydrocarbon Vapor Recovery Unit Model DE 1000

Remaining JP-4 vapors that are not completely or unavoidably removed are vented out an aluminum stack at the top of the unit. Insufficient residence time and/or inadequate contact with the coil surface probably accounts for the incomplete condensation of those constituents with boiling points above the systems operating temperature. Other hydrocarbon constituents with boiling points at or below the operating temperature, such as methane, ethane and ethene, pass freely through the system.

### SECTION III

#### SAMPLING AND ANALYTICAL PROCEDURES

##### HYDROCARBON CONCENTRATION MEASUREMENT (FLAME IONIZATION DETECTORS)

Two Flame Ionization Detector (FID) instruments were used simultaneously to determine hydrocarbon concentrations at the inlet and outlet of the vapor recovery units. Scott Total Hydrocarbon Analyzers (THCAs) Models 215 and 116 were used at the inlet and outlet sites, respectively. Figures 3 and 4 illustrate the various features of the sampling system.

To bring the inlet hydrocarbon concentration measurement into the span range of the Model 215 THCA it was necessary to dilute the inlet gas with hydrocarbon-free air. The mixed gas was then delivered in excess to the THCA on both inlet and outlet systems. An in-line rotameter, prior to the analyzer sample inlet point, helped regulate consistent flow to the detector. Constant detector conditions were maintained by the internal pump pressure regulator and bypass flow valve. The manufacturer's recommended pressure setting of 1.0 lb per square inch and a bypass flow rate of 6 standard cubic feet per hour were used for calibration and sample collection.

A stainless steel lined pump was used to withdraw the hydrocarbon vapors from the inlet pipe, and a tetrafluorocarbon lined pump was used on the outlet side. The temperature of the gas exiting the pumps was monitored during operation. Attempts were made to duplicate sampling temperature conditions when calibrating the dilution system.

The sample collection system was leak-checked before and after each field use. A vacuum gauge and toggle switch upstream of the pump allowed for leak checks of about 20 inches of mercury. If the system failed to hold a vacuum for one minute after isolating the pump, the system was considered to have a significant leak. All leak checks performed after the conclusion of a test run passed.

- 6 -

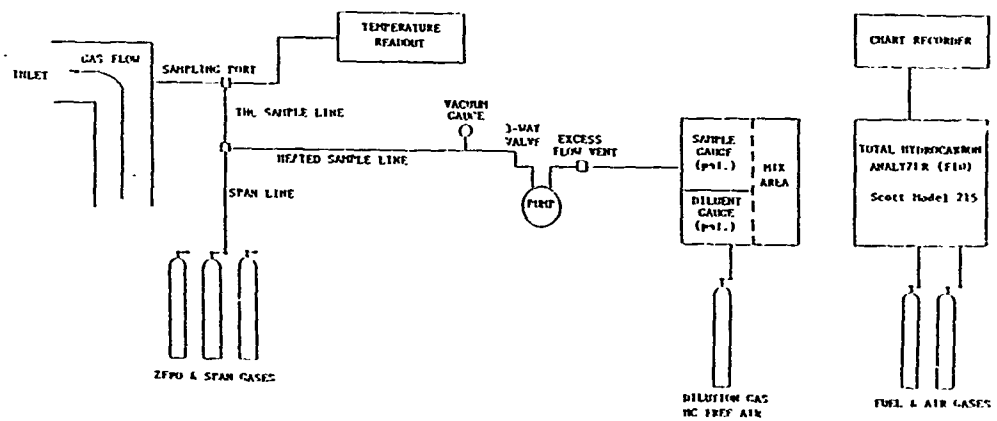

Figure 3. Hydrocarbon Sampling System for Testing the Inlet Duct at the Edwards Vapor Recovery Unit at March AFB, CA

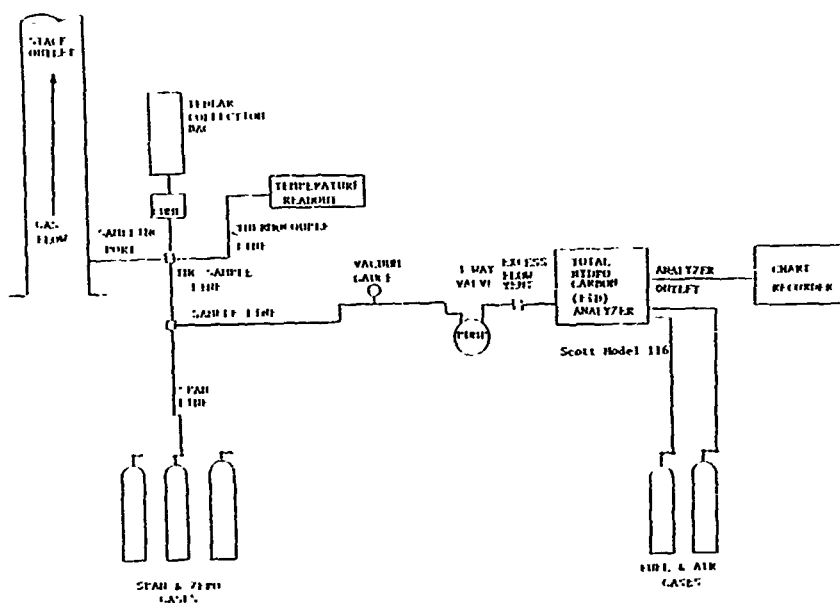

Figure 4. Hydrocarbon Sampling System for Testing the Outlet Duct at the Edwards Vapor Recovery Unit at March AFB, CA

Inlet hydrocarbon vapor concentrations were anticipated to exceed the full span range ( $>100,000$  ppm) of the Scott Model 215 THCA. Thus, the use of a dilution system was imperative. Prior to the field tests, two sample dilution units were partially replumbed to perform the required dilutions.

A Hastings bubblemeter was used to calibrate the gas flow rates through the units' capillary network. Gas flow potentials were determined for different combinations of capillaries and at a range of gauge settings. Gauge settings were controlled by a regulator provided on the units.

One unit was used to deliver diluent gas (zero air with  $<0.1$  ppm THC) while the other was used to deliver calibration gases (methane in air) or sample gases. After exiting their respective dilution units, the two gas streams were combined and provided in excess to the THCA.

These preliminary gas flow rate determinations were used as estimates for use in the field. Prior to each sample collection period, the following steps were taken: (1) the sample collection pump was warmed up to simulate the conditions taking place during a test period (a thermocouple was situated at the outlet of the pump to monitor the temperature), (2) the previously determined gauge settings for the desired dilution were checked with the bubblemeter and noted, (3) the actual, achieved dilution was calculated from the proportional gas flow rates, and (4) the accuracy of the system was verified by diluting a known concentration of span gas (methane) with hydrocarbon-free air at the previously calculated dilution.

The dilution system was then operated at these appropriate settings for the test period. Periodic span and zero checks were made at various intervals depending on the test length.

Following the test, a calculation of the sample delivery rate was made. Similar steps were taken as in the pretest check, but emphasis was put on simulating the pump's outlet temperature that was produced during the test period. The ultimately determined dilution factor was used in the calculation of the concentration of the inlet vapors.

No dilution was necessary for the outlet concentrations. Span gases of 25,200 ppm and 10,100 ppm were used to span the Scott Model 116 THCA.

#### FLOW MEASUREMENT

Total flow was measured by placing a Dresser Industries Roots Meter Model 11 M125 over the vent stack and sealing with silica sealer. The 11,000 cfm maximum capacity of the meter was more than adequate to measure the total flows. Readings were taken each minute during the test runs, except in Run 1 when readings were recorded only at the beginning and end of the run.

#### HYDROCARBON CONSTITUENT MEASUREMENT (GAS CHROMATOGRAPH)

The laboratory analysis for speciating the vapor recovery system inlet and outlet hydrocarbon samplers were conducted using standard gas chromatographic techniques. A Tracor Model 550 Gas Chromatograph equipped with a FID was used. The instrument was interfaced with a Spectraphysics Model SP 2060 Integrating System which provided electronic integration for each chromatogram.

The chromatographic column which was used for all the analyses was commercially prepared by Supelco and was a Durapak, N-Octane/Porasil C, 120/150 mesh, 2.3 mm x 1.5 M, stainless steel. Column temperature was maintained at 25°C, detector temperature was 250°C, carrier gas was nitrogen at a flow rate of 25 cc/min. The gas chromatograph was equipped with a gas sampling valve with 1 cc ambient temperature sample loop.

Instrument calibration was accomplished by using a specialty gas vendor certified calibration gas. The calibration gas was a mixture of C<sub>1</sub> to C<sub>5</sub> hydrocarbons certified accurate to  $\pm 2\%$ . Prior to each set of analyses, the gas chromatograph was calibrated to determine the instrument response (millivolts/ppm) for each component. Since only one column was used, retention time data used for component identification permits only tentative identification.

Each sample was then injected and the results recorded by the SP 2000 Integration System and printed by an SP 4100 Integrator. Those components which fell within a 3% analytical window programmed into the integrator were automatically calculated and converted to ppm. Those which fell outside the window were manually calculated by dividing the area under the curve for each component (millivolts) by the response factor established in the calibration.

#### SECTION IV

##### SUMMARY OF RESULTS

Tables 1 through 4 summarize the hydrocarbon concentrations measured as methane and as corrected for hydrocarbon constituents at both the inlet and outlet sampling locations. The tables also present the mass inlet loading and the mass emission rates from which the efficiencies also are calculated and presented. Test Runs 1, 2, and 3 were conducted at the Panero refueling area, and test Run 4 was conducted at the Pritchard refueling area. On Run 1, shown in Table 1, more credence should be given the overall average mass emission rates and efficiencies than the individual time periods, as Roots meter readings were recorded only at the beginning and end of the test period. Calculations for individual time periods shown in the table for Run 1 were based on an average actual flow rate through the Roots meter. Table 5 lists, in addition to the summary results in Tables 1-4, most of the data taken during the testing and the results of intermediate and final calculations for each of the specific time periods. The symbols in the headings relate to the sample calculations in Appendix A.

The Panero refueling area control system was sampled for a total of 287 minutes during the three runs. Average efficiencies for each of the three runs were 90.7%, 89.9%, and 88.1% for an arithmetic average of 89.6%. Time weighting the average results in an 89.7% overall efficiency. Fuel movement periods dictated the length of the test runs. Run No's. 1 and 3 were therefore only one hour, while Run No. 2 was almost four hours. Time weighting the results was employed because of the difference in the sample times.

Flow rates at Panero corrected to standard conditions of 60°F and one atmosphere ranged from 21 cfm to 58 cfm, averaging 43 cfm. There appears to be an inverse correlation between flow rates and hydrocarbon removal efficiencies at least in the flow rates encountered in this test series. The same relationship seems to exist between inlet loading and efficiency. During the first half of Run 2 however, the lower efficiencies could be the result of the relatively lower flow rates.

Duct temperatures, which reflect condensor temperatures, were normal during the period of that run. In Run 3 the warmer duct temperatures could be the cause of the slightly lower efficiencies measured during that test run.

The one test run at Pritchard showed an average efficiency of 85.7%, somewhat lower than at Panero. Inlet loadings were as high, if not higher, than Panero. The explanation for the lower efficiency could be the combination of warmer duct temperatures, higher gas flows and higher inlet concentrations than those found in two of the three Panero test runs.

Gas chromatographic analyses of the outlet vapors are summarized in Table 6. Hydrocarbons C<sub>1</sub> through C<sub>4</sub> were identified in each sample. C<sub>4</sub> compounds comprised over 50% of every sample total. Constituent analysis of the inlet vapors was not a part of this study. For calculation purposes, a typical JP-4 vapor constituent breakdown at 70°F fuel temperature was used. This analysis, supplied by the Air Force and conducted by Monsanto Research, showed C<sub>4</sub> through C<sub>6</sub> hydrocarbons to predominate.

#### RECOMMENDATIONS

If there is sufficient concern regarding the possible relationship between flow rate (and mass loading) and control efficiency, additional testing is recommended. The current test series was conducted with minimal control over the pumping rates. The apparent relationships could be verified under more controlled conditions.

# APPENDIX A

## MARCH AIR FORCE BASE EXAMPLE CALCULATIONS

### Measured Parameters

- C<sub>I</sub> = Inlet HC concentration, ppm measured as CH<sub>4</sub> (Total Hydrocarbon [HC] Analyzer)
- C<sub>O</sub> = Outlet HC concentration, ppm measured as CH<sub>4</sub> (Total Hydrocarbon [HC] Analyzer)
- Q<sub>AO</sub> = Outlet gas flow, actual cubic feet per minute (Roots Meter)
- T<sub>STD</sub> = Temperature at standard condition
- T<sub>SO</sub> = Outlet gas temperature (type and thermocouple)
- P<sub>STD</sub> = Barometric pressure at standard condition
- P<sub>B</sub> = Barometric pressure
- MW<sub>I</sub> = Inlet average molecular weight
- MW<sub>O</sub> = Outlet average molecular weight
- R<sub>I</sub> = Inlet average carbon number
- R<sub>O</sub> = Outlet average carbon number

Given:

Run #1 Time 1035-1125

- |                              |   |
|------------------------------|---|
| C <sub>I</sub> = 460,096 ppm | Q <sub>AO</sub> = 40 ft <sup>3</sup> /min |
| C <sub>O</sub> = 45,500 ppm  | MW <sub>I</sub> = 70.14*                  |
| T <sub>STD</sub> = 60°F      | MW <sub>O</sub> = 48.48                   |
| T <sub>SO</sub> = -27.8°F    | R <sub>I</sub> = 4.9                      |
| P <sub>STD</sub> = 29.92"Hg  | P <sub>O</sub> = 3.32                     |
| P <sub>B</sub> = 28.36"Hg    |   |

(1) Q<sub>SO</sub> = Outlet flowrate @ standard condition

$$\begin{aligned}
 Q_{SO} &= Q_{AO} \times \frac{T_{STD}}{T_{SO}} \times \frac{P_B}{P_{STD}} \\
 &= 40 \text{ ft}^3/\text{min} \times \frac{520^\circ\text{F}}{432.2} \times \frac{28.36}{29.92} \\
 &= 45.62 \text{ ft}^3/\text{min}
 \end{aligned}$$

\* Calculated from typical JP-4 vapor constituent analysis @ 70°F. The analysis was prepared by Monsanto and supplied to ES by Tom Stauffer, Tyndall AFB.

- (2) Determination of average molecular wt and carbon no. of the outlet gas as per GC analysis

	<u>Mole %</u>	<u>Contribution to Mole Wt</u>	<u>Carbon No.</u>	<u>%</u>	<u>Carbon Contribution to Gas Composition</u>
CH <sub>4</sub>	4.7	0.752	1	4.7	0.047
C <sub>2</sub> H <sub>4</sub>	0.03	0.01	2	11.84	0.236
C <sub>2</sub> H <sub>6</sub>	11.81	3.54	3	30.19	0.906
C <sub>3</sub> H <sub>8</sub>	30.19	13.28	4	<u>53.27</u> 100.00	<u>2.131</u> 3.32 avg. C No.

$$C_4H_{10} \quad \frac{53.27}{100.00} \quad \frac{30.90}{48.48} \quad \text{avg. mol. wt/mole}$$

$$MW_o = (\text{mol. wt of CH}_4 \times \% \text{ CH}_4) + (\text{mol. wt C}_2\text{H}_4 \times \% \text{ C}_2\text{H}_4) + (\text{mol. wt C}_3\text{H}_8 \times \% \text{ C}_3\text{H}_8) + (\text{mol. wt C}_4\text{H}_{10} \times \% \text{ C}_4\text{H}_{10})$$

$$= (16 \times 0.047) + (28 \times 0.0003) + (30 \times 0.1181) + (44 \times 0.3019) + (58 \times 0.5327)$$

$$MW_o = 48.48$$

$$R_o = (\% \text{ of C for CH}_4 \times \%) + (\% \text{ of C for C}_2\text{H}_4 \times \% \text{ total sum for C}_2 \text{ compound}) + (\% \text{ of C for C}_3\text{H}_8 \times \% \text{ total of C}_3 \text{ compound}) + (\% \text{ of C for C}_4\text{H}_{10} \times \% \text{ total sum for C}_4 \text{ compound})$$

$$= (1.0 \times 0.047) + (2 \times 0.1184) + (3 \times 0.3019) + (4 \times 0.5327)$$

$$= (0.047) + (0.236) + (0.906) + (2.131)$$

$$R_o = 3.32$$

- (3) Determination of Q<sub>AF</sub> (air flow rate through the control device @ standard condition)

C<sub>OA</sub> = Actual outlet HC concentration, ppm

$$C_{OA} = \frac{C_o}{R_o} = \frac{45,500}{3.32}$$

$$C_{OA} = 13,705 \text{ ppm}$$

$$B_{HCO} = \frac{C_{O_2}}{1,000,000} = \text{Fraction of HC in outlet gas}$$

$$= \frac{13,750}{1,000,000}$$

$$B_{HCO} = 0.0137$$

$$Q_{AF} = Q_{SO} \times (1 - B_{HCO})$$

$$= 45.62 \text{ ft}^3/\text{min} \times (1 - 0.0137)$$

$$= 44.98 \text{ ft}^3/\text{min}$$

(4) Determination of  $Q_{SI}$  (Inlet gas flow rate at standard condition)

$$C_{IA} = \frac{C_I}{R_I} = \text{Actual inlet HC concentration}$$

$$= \frac{460,096 \text{ ppm}}{4.3}$$

$$C_{IA} = 93,897 \text{ ppm}$$

$$B_{HCI} = \frac{C_{IA}}{1,000,000} = \text{Fraction of HC inlet gas}$$

$$= \frac{93,897 \text{ ppm}}{1,000,000}$$

$$B_{HCI} = 0.0939$$

$$Q_{SI} = \frac{Q_{AF}}{(1 - B_{HCI})}$$

$$= \frac{44.98 \text{ ft}^3/\text{min}}{(1 - 0.0939)}$$

$$Q_{SI} = 49.64 \text{ ft}^3/\text{min}$$

(5) Mass Hydrocarbon Loadings Determination

$M_I$  = Inlet mass hydrocarbon loading

$$M_I = \frac{Q_{SI} \times B_{HCI}}{379 \text{ SCF}} \times M_{uI} \times \frac{60 \text{ min}}{\text{hr}}$$
$$= \frac{49.64 \text{ ft}^3/\text{min} \times 0.0939}{379 \text{ SCF}} \times 70.14 \times \frac{60 \text{ min}}{\text{hr}}$$

$$M_I = 51.75 \text{ lbs HC/hr}$$

$M_O$  = Outlet mass hydrocarbon loading

$$M_O = \frac{Q_{SO} \times B_{CO}}{379 \text{ SCF}} \times M_{uO} \times \frac{60 \text{ min}}{\text{hr}}$$
$$= \frac{45.62 \text{ ft}^3/\text{min} \times 0.0137}{379 \text{ SCF}} \times 48.48 \times \frac{60 \text{ min}}{\text{hr}}$$

$$M_O = 4.80 \text{ lbs HC/hr}$$

HC Removal Efficiency =  $\Sigma E$

$$\Sigma E = \frac{M_I - M_O}{M_I} \times 100$$
$$= \frac{51.75 - 4.76}{51.75} \times 100$$
$$= \frac{46.99}{51.75} \times 100$$

$$\Sigma E = 90.7\%$$
